

# Genomic Selection in Crossbreeding Programs

Jack Dekkers

1

## Current Pyramid Selection Programs

- Limitations:
- limited selection for performance in the field
  - no selection for traits not recorded in nucleus - disease
  - no selection for heterosis

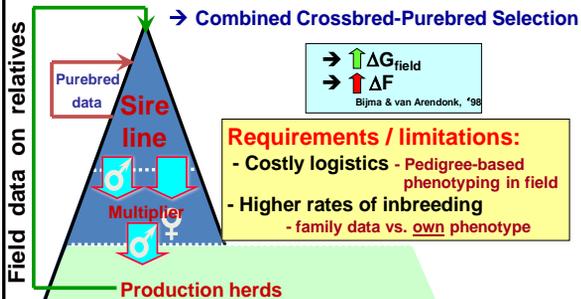

## Selection for Performance in Field

'Traditional' Breeding Solution:

Collect phenotypes on relatives in field

→ Combined Crossbred-Purebred Selection

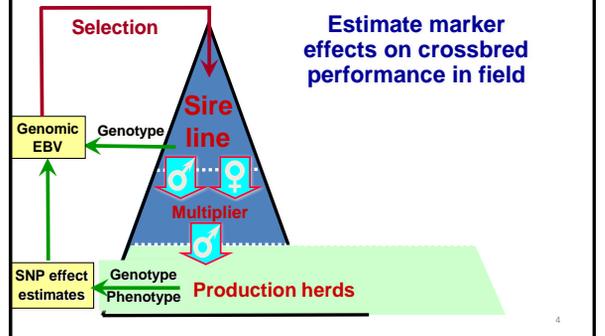

3

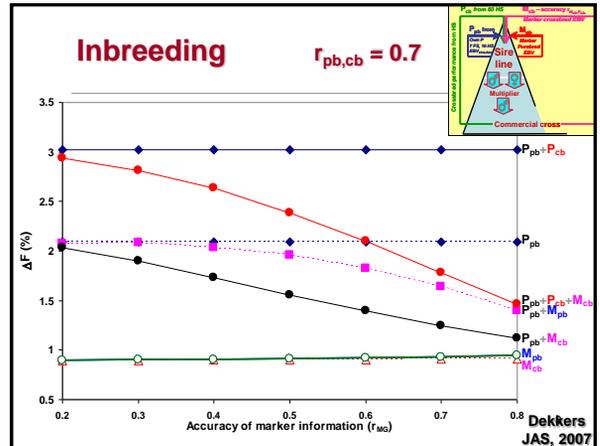

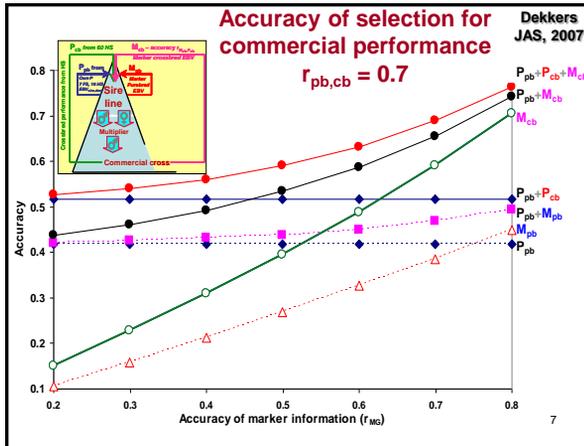

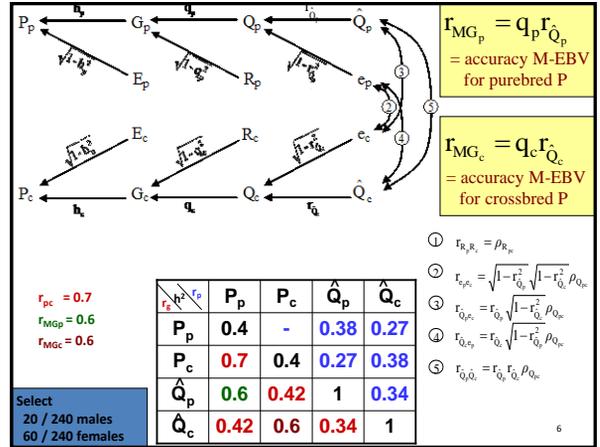

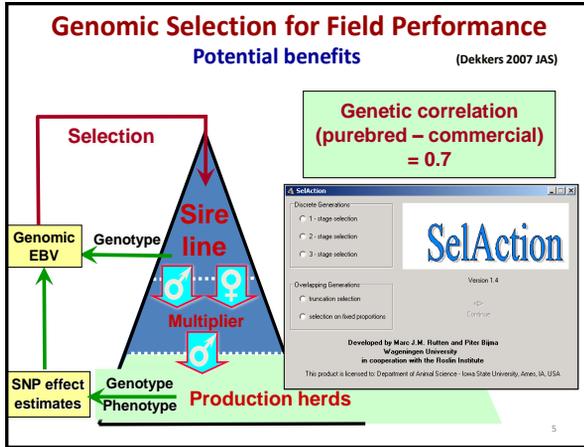

## Selection for Performance in Field

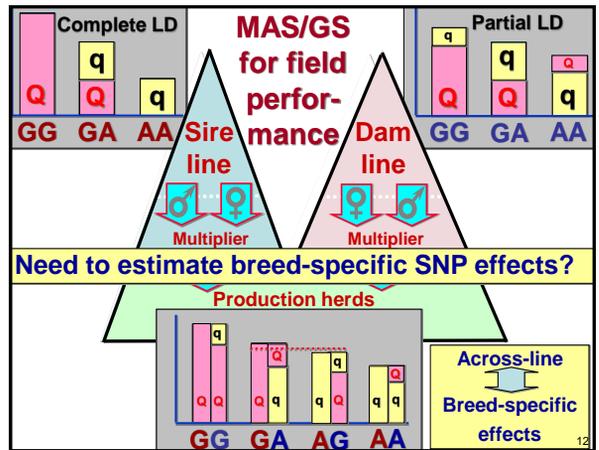

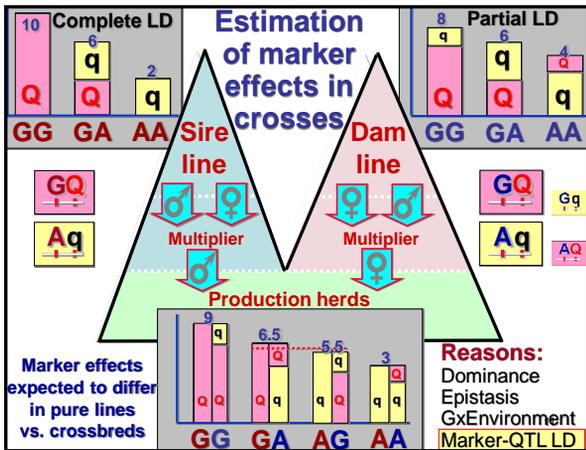

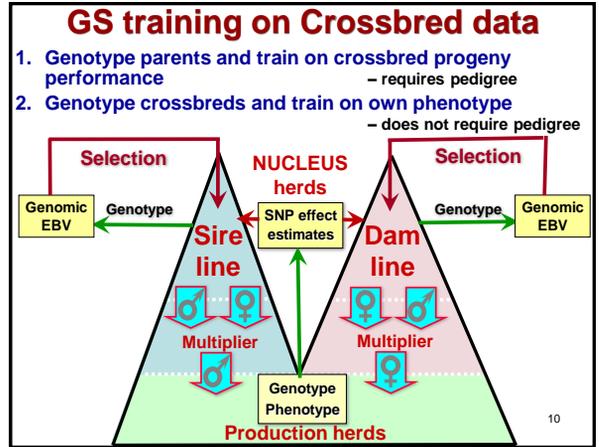

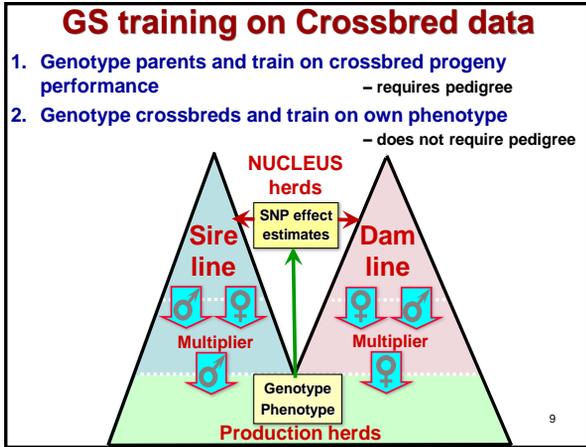

Possible Genomic Selection Solution:

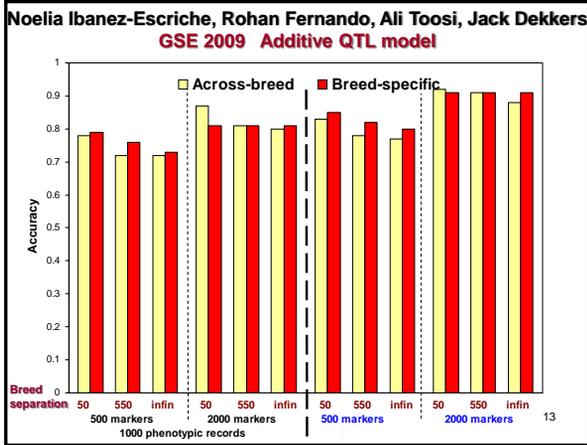

Estimate marker effects on crossbred performance in field

4

### Impact of Dominance

$p_S$	Sire Breed			$p_D$	Dam Breed		
$q_S$	BB	Bb	bb	$q_D$	BB	Bb	bb
Freq.	$p_S^2$	$2p_Sq_S$	$q_S^2$	Freq.	$p_D^2$	$2p_Dq_D$	$q_D^2$
Value	a	d	-a	Value	a	d	-a

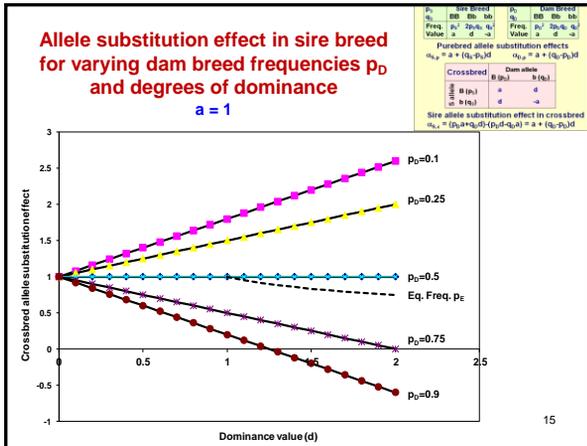

**Purebred allele substitution effects**  
 $\alpha_{S,p} = a + (q_S - p_S)d$        $\alpha_{D,p} = a + (q_D - p_D)d$

S allele	Crossbred	Dam allele	
	B ( $p_S$ )	a	d
	b ( $q_S$ )	d	-a

**Sire allele substitution effect in crossbred**  
 $\alpha_{S,c} = (p_D a + q_D d) - (p_D d - q_D a) = a + (q_D - p_D)d$

→ Allele substitution effect in one parental breed depends on allele freq.s in other parental breed → Breed-specific allele effects

14

### Impact of Dominance

$p_S$	Sire Breed			$p_D$	Dam Breed		
$q_S$	BB	Bb	bb	$q_D$	BB	Bb	bb
Freq.	$p_S^2$	$2p_Sq_S$	$q_S^2$	Freq.	$p_D^2$	$2p_Dq_D$	$q_D^2$
Value	a	d	-a	Value	a	d	-a

**Purebred allele substitution effects**  
 $\alpha_{S,p} = a + (q_S - p_S)d$        $\alpha_{D,p} = a + (q_D - p_D)d$

S allele	Crossbred	Dam allele	
	B ( $p_S$ )	a	d
	b ( $q_S$ )	d	-a

**Sire allele substitution effect in crossbred**  
 $\alpha_{S,c} = (p_D a + q_D d) - (p_D d - q_D a) = a + (q_D - p_D)d$

→ Allele substitution effect in one parental breed depends on allele freq.s in other parental breed → Breed-specific allele effects → Effects change over time

→ Estimate 'a' and 'd' vs allele substitution effects

## Genomic selection of purebred animals for crossbred performance in the presence of dominant gene action

Jian Zeng<sup>1</sup>, Ali Toosi<sup>2</sup>, Rohan I. Fernando<sup>1\*</sup>, Jack CM Dekkers<sup>3</sup> and Dorian J Garrick<sup>1</sup>

**Abstract**  
**Background:** Genomic selection is an appealing method to select purebreds for crossbred performance. In the case of crossbred records, single nucleotide polymorphism (SNP) effects can be estimated using an additive model or a breed-specific allele model. In most studies, additive gene action is assumed. However, dominance is the likely genetic basis of heterosis. Advantages of incorporating dominance in genomic selection were investigated in a two-way crossbreeding program for a trait with different magnitudes of dominance. Training was carried out only once in the simulation.  
**Results:** When the dominance variance and heterosis were large and overdominance was present, a dominance model including both additive and dominance SNP effects gave substantially greater cumulative response to selection than the additive model. Extra response was the result of an increase in heterosis but at a cost of reduced purebred performance. When the dominance variance and heterosis were realistic but with overdominance, the advantage of the dominance model decreased but was still significant. When overdominance was absent, the dominance model was slightly favored over the additive model, but the difference in response between the models increased as the number of quantitative trait loci increased. This reveals the importance of exploiting dominance even in the absence of overdominance. When there was no dominance, response to selection for the dominance model was as high as for the additive model, indicating robustness of the dominance model. The breed-specific allele model was inferior to the dominance model in all cases and to the additive model except when the dominance variance and heterosis were large and with overdominance. However, the advantage of the dominance model over the breed-specific allele model may decrease as differences in linkage disequilibrium between the breeds increase. Retaining is expected to reduce the advantage of the dominance model over the alternatives, because in general, the advantage becomes important only after five or six generations post-training.  
**Conclusion:** Under dominance and without retraining, genomic selection based on the dominance model is superior to the additive model and the breed-specific allele model to maximize crossbred performance through purebred selection.

## Breed-Specific SNP Allele Mode (BSAM)

$$y_i = \mu + \sum_{j=1}^k (X_{ij}^A \alpha_j^A + X_{ij}^B \alpha_j^B) + e_i$$

- $X_{ij}^A$  or  $X_{ij}^B \in \{0, 1\}$  is the copy number of a given allele at SNP  $j$  of breed origin A or breed origin B
- $\alpha_j^A$  or  $\alpha_j^B$  is the breed-specific substitution effect for the allele of breed origin A or B
- The SNP allele effects have breed-specific variance  $\sigma_{\alpha^A}^2$  and  $\sigma_{\alpha^B}^2$ , and breed-specific  $\pi$  parameter  $\pi_{\alpha^A}$  and  $\pi_{\alpha^B}$

18

## Dominance Model

$$y_i = \mu + \sum_{j=1}^k (X_{ij} a_j + W_{ij} d_j) + e_i$$

- $W_{ij} \in \{0, 1\}$  is the indicator for heterozygous genotype
- $a_j$  is the additive effect and  $d_j$  the dominance effect
- $d_j | \mu_d, \sigma_d^2 = \begin{cases} 0 & \text{with probability } \pi_d \\ \sim N(\mu_d, \sigma_d^2) & \text{with probability } 1 - \pi_d \end{cases}$
- $\mu_d | \sigma_d^2 \sim N(\eta, \sigma_d^2 / \phi)$ , where  $\eta = \frac{H}{\sum_j (p_j^2 - p_j)^2}$  and  $\phi$  measures the strength of the prior belief in terms of  $\sigma_d^2$

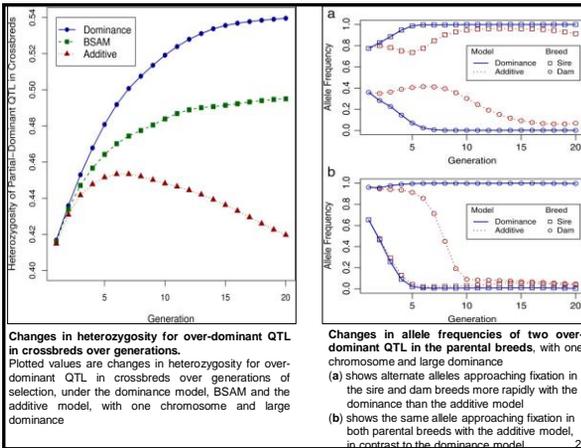

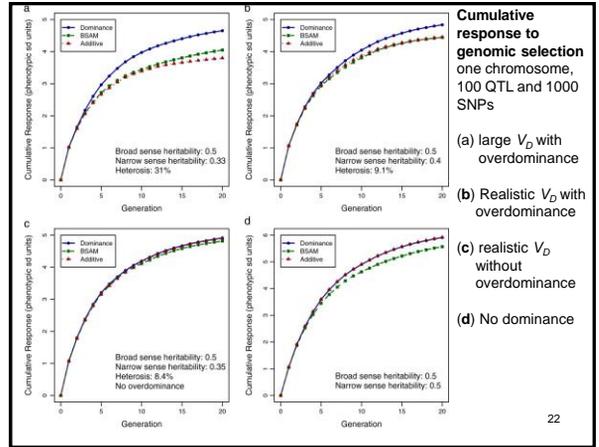

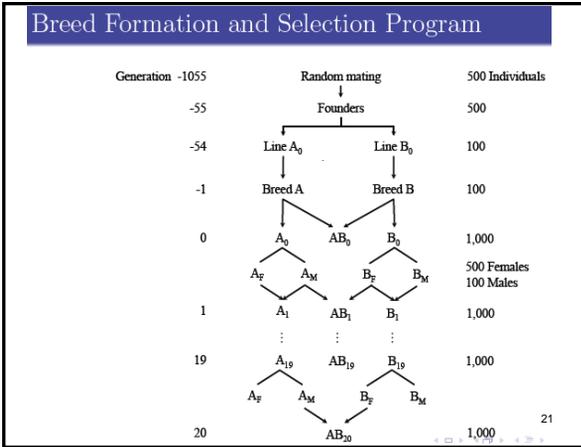

19

## Design of Study

Scenario	Gene Action	$h_{BS}^2$	$h_{NS}^2$	Heterosis
1	Overdominance	0.5	0.33	31%
2	Overdominance	0.5	0.4	9.1%
3	Incomplete Dominance	0.5	0.35	8.4%
4	Additive	0.5	0.5	0

- Other parameters, such as LD, allele frequencies, QTL positions, etc, were kept constant across scenarios
- Training was carried out only once

20

## Conclusions

**Genomic Selection provides great opportunities for genetic improvement of commercial crossbred performance**

- Can substantially increase rates of response for commercial crossbred performance
- Reduces rate of inbreeding - Compared to CCPS
- Requires statistical methods for estimation of marker-effects in crossbred populations
  - Breed-specific allele models
  - **Dominance models**
